

ABSTRACT OF THE DISCLOSURE

A lopper shear pull-rope grip comprises a closed end at its top. The through hole of the bulge is connected to the hollow notch of the grip, where a rope can punch through hole. And, a slanting board extends downwards from a turning site of the through hole connecting to the hollow notch. The slanting board is provided with a conductive rim. Moreover, through notches are mounted at the front and back of the projecting grip under the bulge. A pulley has a hollow structure, where a rim shall be provided externally to have it installed between the through notches at front and back of grip. Thus, the pulley can slide smoothly along the slanting board of the grip. Thereupon, the pulley can be pushed over the slanting board, where the rope shall be clamped into another turning site of the through hole connecting to hollow notch. When the rope is pulled upwards, the pulley will clamp the rope more compactly so as to adjust and position the rope rapidly for convenient and loose-free usage.
